# **ASK<sup>TM</sup> VIDEO PLUS Software**

**“Glass Teletype” Software**

for use with the

**AIM - SYM - KIM**

and the

**VIDEO PLUS**

## Description of the ASK VIDEO PLUS Software

This software package makes the VIDEO PLUS much easier to interface with the AIM, the SYM and the KIM. It has been developed in response to a number of requests and suggestions from VIDEO PLUS owners. The basic features of this new package are:

1. It will work with the AIM, SYM or KIM without modification. The program contains code to determine which microcomputer is being used and makes all necessary adjustments automatically. The program can be placed in EPROM and still be used on all three micros.
2. It interfaces directly to the AIM and SYM monitor via their provisions for OUTPUT and/or INPUT vectors, and it sets up these vectors automatically during initialization of the program.
3. It supports an ASCII keyboard so that a keyboard may be added to the AIM, SYM or KIM with full UPPER and lower case capabilities.
4. It works directly with AIM BASIC and SYM BASIC.
5. It supports the following control functions:

Carriage Return		CR	Position Cursor at start of next line
Home		↑H	Position Cursor at upper left corner
Up/Down/Left/Right		↑U ↑D ↑L ↑R	Move Cursor without altering screen contents
Scroll		↑S	Automatic and Manual Scroll
Upper Case Mode		↑A	Automatically convert alpha characters to upper case
Lower Case Mode		↑A	Permit lower case characters, even on SYM
Echo		↑F	Automatic Echo may be selected or suppressed
Parity/PCG Characters		↑P	Bit 80 may be permitted or suppressed
Auto Linefeed		↑Q	Linefeed following Carriage Return may be suppressed
Escape/Break	[↑B]	ESC	Return to AIM/SYM/KIM Monitor from Keyboard
Delete	[_]	DEL	Delete characters in Editor, BASIC, Monitor
Input from Display		↑Z	Read characters from Display instead of Keyboard
Erase		↑E	Erase Display from Cursor to End of Screen
Clear		↑X	Clear the entire Display
	[SYM Control Code]		

6. It automatically adjusts to 40 character TV mode or 80 character Monitor mode.
7. The program is totally position independent. It may be placed anywhere in memory [except pages zero and one, of course], may be placed in EPROM, may be moved from one of the ASK family micros to another without modification, and does not require any user programming [except for a short startup program on the KIM]. The user sets the A register to a specified value and starts the program at the video initialization address. The keyboard is separately initialized by executing the keyboard initialization routine.
8. Since the KIM does not have INPUT and OUTPUT vectors, a method of having user defined INPUT and OUTPUT locations initialized on the KIM is supported. It is very easy, for example, to use this software with the MICRO-ADE Assembler/Disassembler/Editor package without modification!

## ASK VIDEO PLUS Loading Instructions

The ASK VIDEO PLUS tape contains four files recorded in the standard KIM cassette tape format. This format may be loaded by the AIM, SYM or KIM. The AIM or SYM owner can load the tape in KIM format once, and then save it in the higher speed format supported by his AIM or SYM. A KIM owner who has "Hypertape" can save it in this format.

**SYNCS:** The first file on the tape is 1024 SYNC characters. This may be used, with the suitable program provided with your AIM, SYM, or KIM to adjust your tape recorder to the optimal value for reading the remainder of the tape.

**MEMORY TEST [ID 10]:** The Memory Test is the same as that listed in the VIDEO PLUS Manual. It loads into 0000 through 00D8 and can be used to test RAM. Put the address of the first page to be tested into 0000; the address of the last page to be tested into 0001; start the program at 0002. If no errors are encountered, then the program will stop with the LED display containing the address following the highest address tested. Otherwise, it will stop on the address with the error. See the VIDEO PLUS Manual or UPDATE 1 for details.

**ASK VIDEO PLUS [ID 20]:** This loads into 4000 through 4546. This is the space normally allocated to the VIDEO PLUS Display RAM. Set the switch on your VIDEO PLUS to the 4000 setting before loading this program.

AIM: Set A408 to 5A for KIM format tape. Use the K device for input. Filename is 20.

SYM: Use LD1 to load KIM format tape. Program ID is 20.

KIM: Normal load with Program ID of 20. If you wish to force load it to some other address, set 17F5/17F6 to the desired address, cue the tape to this third tape file, set 17F9 to FF. If ID 20 is used, then the program will load into 4000.

The program may **NOT** be run at 4000! This is the display memory. It must be moved to wherever in memory you plan to normally run it. Since the code is totally position independent, where you put it depends on the configuration of your system. If you are not currently using the Programmable Character Generator RAM on the VIDEO PLUS, then this is a handy place. A natural place for the AIM would be to have the VIDEO PLUS set for 8000 [Display RAM] and the program at 9000 [Programmable Character Generator RAM]. A natural place for the SYM would be to have the VIDEO PLUS set for 6000 and the program at 7000. Since the KIM has so much open space, the VIDEO PLUS and program might be placed almost anywhere. The ASK VIDEO PLUS Software does not have to be located in the VIDEO PLUS memory. If it is located in the VIDEO PLUS memory, then the initialization process is a little simpler. If it is located somewhere else, then the user must provide an initialization table which will be described below.

**BMOVE [30]:** The KIM user can force load the ASK VIDEO PLUS program anywhere he wants using the KIM loader. The SYM user can move the program after loading it, by using the BMOVE command of the SYM Monitor. The AIM user needs some way to move the program. This BMOVE program loads into 0000. Locations 0000/0001 are set to the FROM address, 0002/0003 are set to the TO address, and 0004/0005 are set to the number of bytes to be moved. For example, to move the ASK program from 4000 to 5000, with the program 546 bytes long [4000 through 4545], the values would be:

0000 00, 0001 40, 0002 00, 0003 50, 0004 46, 0005 05.

The program starts at 0006. After running, the ASK program would now be located at 5000 through 5545. The BMOVE program is a useful utility and will work on the AIM, SYM, or KIM.

Once the program has been moved to its "final resting place", it should be saved on tape in your system's high speed format. The KIM can dump it using "Hypertape" [see **MICRO #1**, "Hypertape and Ultratape", pgs 13-16, or **Best of MICRO Volume 1**, pgs 8-11]. The SYM can use the Save 2 command. The AIM can use its normal dump, but must remember to first restore location A408 to C7 and then use T as the output device.

### Initializing the ASK VIDEO PLUS Software

**AIM:** If the ASK program is located in VIDEO PLUS memory, in the PCG RAM at 5000, then the following steps will initialize the video as output device:

1. **A = EA**                    Make SETUP call Video Init.
2. **\* = 5500**                Set Program Counter to start of SETUP.
3. **G/**                        Execute SETUP and VIDEO Initialization

All output that would normally go to the LED display will now appear on the video monitor. **Caution:** Do not put the AIM into Single Step Mode. This will bomb the video program.

You can now use the AIM Monitor, Editor and BASIC with output going to the display. A note about the Editor: the maximum width of a line for the Editor is 60 characters. If you exceed this limit, the additional characters will be lost. They will appear on the screen as you type them, but will not be placed into the Editor buffer. So, be careful. You can change the screen parameters so that the line length is only 60 characters wide. See **COLROW Subroutine**.

If the ASK VIDEO PLUS program is **NOT** in the VIDEO PLUS memory space, then a slightly different procedure is required. Assume for this example that the program is at 2000 and the VIDEO PLUS is selected at 8000:

1. **A = 00**                    Make SETUP return to Monitor.
2. **\* = 2500**                Set Program Counter to start of SETUP.
3. **G/**                        Execute SETUP.
4. **A = 80**                    Set A to start of VIDEO PLUS Display RAM at 8000.
5. **X = ED**                    Low address of Initialization TABLE.
6. **Y = 23**                    High address of Initialization TABLE.
7. **\* = 2067**                Address of USER Entry to VIDEO Initialization.
8. **G/**                        Execute USER VIDEO Initialization.

If the standard TABLE is not used, then X and Y must be set to point at an equivalent initialization table. See page 14 of the listing for the TABLE characteristics and values.

If you desire to use an external ASCII keyboard connected to the VIDEO PLUS, and assuming the ASK program is at 5000, the initialization procedure consists of:

1. **\* = 5400**                Set Program Counter to Keyboard Initialization.
2. **G/**                        Execute the Keyboard Initialization.

The ASCII keyboard is not setup as the USER Input device. It can not be used with the Monitor or Editor since they go directly to the AIM Keyboard or a TTY. The ASCII keyboard may be used with BASIC. Run BASIC using the normal 5 command. Set Memory Size as desired and Width will default to 60 characters. When BASIC starts, it is getting input from the AIM Keyboard. To switch to the ASCII Keyboard, location A412 must be changed to a "U" or hex 55. The following statement will accomplish this:

**POKE 42002,85** Where 42002 = A412 hex and 85 = 55 hex.

Input will now come from the ASCII Keyboard. It will initially be in UPPER case. Use CTRL A to toggle between UPPER and lower case modes. Remember, BASIC commands must be in UPPER case. To return to the AIM Keyboard for input:

**POKE 42002,13** Where 42002 = A412 hex and 13 = 0D or CR.

To restore the LED's as the output device, the following program may be used. This simply changes the output vector back to the LED service routine. A similar routine allows switching back to the video for output.

```

0200 A9 05                LDAIM $05        LED SERVICE AT EF05            Set Output to LED's
0202 8D 06 A4            STA    $A406    OUTPUT VECTOR AT A406, A407
0205 A9 EF               LDAIM $EF
0207 8D 07 A4            STA    $A407
020A 00                 BRK             RETURN TO MONITOR

020B A9 9F               LDAIM $9F        VIDEO SERVICE AT XX9F         Set Output to VIDEO
020D 8D 06 A4            STA    $A406    LOW ADDRESS OF OUTTV
0210 A9 51               LDAIM $51        HIGH ADDRESS = PROGRAM START
0212 8D 07 A4            STA    $A407    ADDRESS + 1
0215 00                 BRK             RETURN TO MONITOR

```

**SYM:** If the ASK program is located in VIDEO PLUS memory, in the PCG RAM at 5000, then the following steps will initialize the video as output device [**BOLD** represents the user input, *ITALIC* represents the SYM output]:

1. **REG CR P → S →**  
**F → A EA CR** Make SETUP call Video Initialization.
2. **GO 5500 CR** Execute SETUP and VIDEO Initialization

All output that would normally go to the LED display will now appear on the video monitor. You can now use the SYM Monitor, Editor and BASIC with output going to the display.

If the ASK VIDEO PLUS program is **NOT** in the VIDEO PLUS memory space, then a slightly different procedure is required. Assume for this example that the program is at 2000 and the VIDEO PLUS is selected at 6000:

1. **REG CR P → S →**  
**F → A 00 CR** SETUP returns to Monitor, if A = 00.
2. **GO 2500 CR** Execute ASK SETUP.
3. **REG CR P → S →**  
**F → A 60 →** Set A to start of VIDEO PLUS Display RAM at 6000.
4. **X ED →** Low address of Initialization TABLE.
5. **Y 23 CR** High address of Initialization TABLE.
6. **GO 2067 CR** Execute at USER Entry to VIDEO Initialization.

If the standard TABLE at 23ED is not used, then X and Y must be set to point at an equivalent initialization table. See page 14 of the listing for the TABLE characteristics and values.

If you desire to use an external ASCII keyboard connected to the VIDEO PLUS, and assuming the ASK program is at 5000, the initialization procedure consists of:

1. **GO 5400 CR** Execute the Keyboard Initialization.

The ASCII keyboard is now setup as the Input device. It can be used with the Monitor, Editor, or BASIC, since they all go through the Input and Output Vectors. Run BASIC by a **GO C000 CR** command. Set Memory Size as desired and Width will default to 60 characters. It will initially be in UPPER case. Use CTRL A to toggle between UPPER and lower case modes. Remember, BASIC commands must be in UPPER case.

To restore the LED's as the output device, the following command may be used. This simply changes the output vector back to the LED service routine. **SD 8900,A664 CR** where 8900 is the address of the standard display output routine, HDOUT, and A664 is the address of OUTVEC. A similar command allows switching back to the video for output. **SD 519F,A664 CR** where 519F is the entry to the video output service, assuming the program starts at 5000.

**KIM:** If the ASK program is located in VIDEO PLUS memory, in the PCG RAM at 5000, then the following steps will initialize the video as an output device, the keyboard as an input device, will set up a vector that can be used to test whether or not the keyboard has a character present, and will then permit the user to type to the display:

1. Enter the following program anywhere in free memory:

```
0200 A9 EA      INIT   LDAIM $EA      RUN SETUP AND VIDEO INIT
0202 20 00 55          JSR   SETUP  ASSUME PROGRAM AT 5000
0205 20 00 54          JSR   KBINIT  INIT KEYBOARD
0208 20 00 00  IN     JSR   KBTEST  IS THERE ANY DATA PRESENT
020B 90 FB          BCC   IN      WAIT FOR IT. THIS IS NOT REQUIRED
020D 20 00 00          JSR   KBWAIT  GET DATA FROM KEYBOARD
0210 20 00 00          JSR   OUTTV   OUTPUT IT
0213 4C 08 02          JMP   IN      GET MORE
```

ACTUAL VALUES OF KBTEST, KBWAIT AND OUTTV  
WILL BE FILLED IN BY INITIALIZATION.

2. In address 0000/0001 put the address of the Output Vector, in this example 0211. In address 0002/0003 put the address of the Keyboard Test Vector, in this example 0209. In address 0004/0005 put the address of the Keyboard Input Vector, in this example 020E.

3. Enter address 0200 and press GO. The display will initialize and clear. Whatever is typed will appear on the screen with all of the control functions working: up, down, erase, and so forth. If the program is stopped and the locations pointed to by 0000 through 0005 at initialization time are examined, it will be found that these location now contain the addresses of the ASK routines: 0209/020A have 7D/54, the address of KBTEST [547D]; 020E/020F have 8E/54 [548E], the address of KBWAIT; and 0211/0212 have 9F/51 [519F], the address of OUTTV. These values will of course change if the ASK Software is moved to other locations in memory.

The KIM Monitor does not have any provision for changing its basic input and output vectors. It always gets data from the hexpad or TTY and always sends data to the LEDs or TTY. There is, unfortunately, no way around this, but most available programs do support input and output through vectors which can be set to interact with the ASK VIDEO PLUS Software.

If you are planning to use ASK VIDEO PLUS with an existing program, then find where the I/O is vectored through, and put the address of the Output Vector in 0000/0001, the Keyboard Test Vector (if any) in 0002/0003, and the Keyboard Input Vector in 0004/0005. Run the following program and you should be in business. For example, **MICRO-ADE** has its Output Vector at 2EA1, its Input Vector at 2E9E, and does not have a Keyboard Test Vector. The initial vector pointers would therefore be set:

0000 A1, 0001 2E, 0002 FE, 0003 FF, 0004 9E, 0005 2E

Since there is no Keyboard Test Vector, its pointer was set to FFFE, which being a KIM ROM location can not be modified and will not be adversely affected by the attempt of the Keyboard Initialization to modify it.

If the ASK VIDEO PLUS program is **NOT** in the VIDEO PLUS memory space, then a slightly different procedure is required. Assume for this example that the program is at 2000 and the VIDEO PLUS is selected at 6000:

1. Enter the following program:

```

0200 A9 60      INIT   LDAIM $60      RUN SETUP AND RETURN
0202 20 00 25      JSR    SETUP  ASSUME PROGRAM AT 2000
0205 A9 60      LDAIM $60      DISPLAY RAM PAGE ADDRESS
0207 A2 ED      LDXIM $ED      LOW TABLE ADDRESS
0209 A0 23      LDYIM $23      HIGH TABLE ADDRESS
020B 20 58 00      JSR    TTABLE  INIT VIDEO
020E 20 00 54      JSR    KINIT   INIT KEYBOARD
0211 20 00 00      IN     JSR    KBWAIT  GET DATA FROM KEYBOARD
0214 20 00 00      JSR    OUTTV   OUTPUT IT
0217 4C 11 02      JMP    IN      GET MORE

```

ACTUAL VALUES OF KBTEST, KBWAIT AND OUTTV  
WILL BE FILLED IN BY INITIALIZATION.

2. Enter 0200 and GO.

If the standard TABLE at 23ED is not used, then X and Y must be set to point at an equivalent initialization table. See page 14 of the listing for the TABLE characteristics and values.

### ASK VIDEO PLUS Program Notes

The following information is, in general, not required for **using** the ASK software, but is useful in **understanding** how it works. It is included to make the total package more useful. One note: all addresses are given as they are in the listing, that is, relative to zero. To find the actual address in a particular configuration, simply add the base address of where the program is residing to the address given. For example, the Initialization Table is listed at 03ED. If the ASK Software is at 5000, then the Table is at 53ED.

1. **Initialization Table [03ED]:** This TABLE contains the information that is required to initialize the ASK Software, in particular that required by the CRT Controller 6845. See the 6845 Data Sheet included with the VIDEO PLUS Manual for additional detail. The TABLE has the following values and functions:

Address	Hex	Dec	Function
03ED	7A	122.	Horizontal Total in Character Time
03EE	50	80.	Horizontal Characters Displayed
03EF	60	96.	Horizontal Sync Position
03F0	0A	10.	Horizontal Sync Width - a fudge factor!

Note: The Horizontal values are divided in half when operating in the TV mode. This is automatically done by the ASK Software and should be taken into account when setting up or modifying an Initialization Table.

03F1	13	19.	Vertical Total - 1 in Character Lines
03F2	1E	30.	Vertical Total Adjust - a fudge factor!
03F3	14	20.	Vertical Lines Displayed
03F4	14	20.	Vertical Sync Position

Note: The Vertical values are not changed for the TV mode.

03F5	00	0.	Scan Mode: Non-interlace.
03F6	0C	12.	Maximum Scan Line Address: 0 - 12 = 13 Scan Lines
03F7	4C	76.	Cursor Blink Rate [40] and Cursor Raster Start [0C]
03F8	0C	12.	Cursor Raster End
03F9	00	0.	Start Address High or Offset into Display Memory initially at zero
03FA	00	0.	Start Address Low
03FB	00	0.	Cursor Address High is initially zero
03FC	00	0.	Cursor Address Low is initially zero

2. **Important Program Locations:** There are several locations in the program that make interacting with it simple. All addresses are as given in the listing.

**SETUP [0500]:** This routine is used to establish where the ASK VIDEO PLUS Software is currently residing. It sets up a subroutine return [RTS] on page zero, does a subroutine call to this return [JSR], and then pulls the return address off the stack to determine where it is in memory. It then uses this information to calculate the starting address of the ASK Software which is the beginning of the JUMP processor. It puts a vector to the JUMP processor into 0178. If the ASK Software was located at 5000, then the following would be placed into memory: **0178 4C 00 50**. This is a JMP to 5000, the start of the JUMP processor. Similarly, a JMP to the SUBR processor is placed into memory: **017B 4C 05 50**. These two jump vectors are used whenever the resident ASK Software needs to make an internal JMP or JSR. SETUP now determines what it should do next as a function of the value that was in the A register initially. If A was 00, then a BRK is executed. If A was 60, then an RTS is executed. If A was EA, then SETUP transfers directly to the video initialization at TTABLE [0058].

**Video Initialization [TTABLE 0058]:** There are two ways to initialize the video. The first assumes that the TABLE of initialization values at 03ED is the correct one to use and that the ASK Software is resident somewhere on the VIDEO PLUS board, in RAM or ROM - it doesn't matter. If this is true, then the entry is at 0058. The pointers to the TABLE are corrected using the data in 0179/017A, and the beginning of the Display Memory RAM is calculated from the program address. If the above assumptions are not true, then entry must be made at **USER [0067]**. The A register must contain the Display RAM Page Number, e.g. 40 if the RAM is at 4000; X is the low address of an initialization table [ED if the standard table is to be used]; and Y is the high address of the initialization table [23 if the ASK Software is at 2000]. The initialization routine calculates the CRT Controller address; tests for up to 8 pages [2K] of Display RAM; determines whether the microcomputer is an AIM, SYM, or other [probably KIM]; checks the TV/Monitor jumper; and then initializes the CRT Controller. If the TV switch/jumper is set for TV, then the horizontal values are divided by 2, so that 80 character per line in the table becomes 40 character per line to the controller. A call is made to the **COLROW** subroutine which sets up the row and column limits and calculates the screen size. The output vectors for the AIM, SYM, or other [KIM] are now set to point to **OUTTV**, the ASK Software entry point for video output. The cursor is HOME'd and the screen cleared and control is returned to the user. An AIM or SYM make a BREAK to the Monitor. The KIM [or other] makes an RTS.

**JRTN [0000] and SRTN [0005]:** All internal JMP's or JSR's are shown in the listing as: **JMP ADDR, NOP, NOP** or **JSR ADDR, NOP, NOP**. This is not what is actually in memory. The code in memory for a JMP is actually: **JSR 0178, ADDR LO, ADDR HI**, where 0178 is the vector to the JUMP processor, and ADDR LO/ADDR HI are the low and high address of the ADDR (or whatever) location relative to the start of the ASK Software. The code for a JSR is identical except that the JSR goes to 017B. The JUMP and SUBR processors use the return pointer on the stack to retrieve the next two bytes of memory which are the relative offset of the desired address. These are added to the starting address of the ASK Software and a JMP is made to the correctly modified address. The only difference between the JUMP and SUBR processors is that the JUMP processor must correct the stack pointer to remove the unwanted JSR return. Examination of the **JRTN [0000]** and **SRTN [0005]** routine listings will provide additional details.

**KBINIT [0400]:** The video must be initialized before the keyboard. KBINIT first sets up the KBTEST and KBWAIT vectors, storing them in the appropriate vectors for the AIM, SYM or KIM. The VIA 6522 is then initialized to permit the input of data through the I/O port on the VIDEO PLUS. An AIM or SYM return to the Monitor via a BRK; the KIM returns via an RTS.

**KBTEST [047D]:** When KBTEST is called by the SYM or KIM (there is no provision for a keyboard test on the AIM) it tests the VIA to determine if any data is present. If there is data present, then the carry bit is set. If there is no data present, then the carry bit is cleared. By testing the carry bit upon return from a KBTEST call, the calling program can determine whether or not there is data present on the keyboard.

**KBWAIT [408E]:** When KBWAIT is called it first determines whether the call was from an AIM. If so, it must then test the carry bit to determine if this is an initialization call or a data call. If the carry bit is clear, then it is an initialization call. Since the initialization has already taken place, no further action is required and a return is made. Otherwise, and always for a SYM or KIM, the keyboard is tested for data. If no data is present, then the test is repeated until data is present. When data is present, it is read in via the VIA. A flag is tested to see if only UPPER case is permitted, or if lower case is permitted as well. If only UPPER case is permitted, the lower case alphabetic characters, "a" to "z" are converted to upper case "A" to "Z". An AIM or KIM then test for the Echo Flag. If it is set, they echo the character via **OUTTV**. If it is not set, they return to the calling routine with the character in the A register. A SYM first tests its own echo flag in TECHO. If its echo flag is set, or if the ASK echo flag is set, then it echos. Otherwise it modifies the return to the SYM by adding 0C to the return address on the stack to skip around the automatic UPPER case conversion routine in the SYM.

**OUTTV [019F]:** This is the entry point to output a character, or service a control code, to the video. The A, X, and Y registers are saved and a test is made to insure that the cursor is within the screen window. If not, it is restored to the home position. A series of tests are now performed to determine if the character supplied in the A register is a command character. If it is a command character for the microcomputer being run, then it is serviced. If it is not, then it is displayed. All registers are restored before a final return is made. The calling program should **not** try to use the subroutines directly, since the final path always restores the registers and removes one level of stack. It is much easier for the calling program to put the command character in the A register and call OUTTV.

**COLROW [0139]:** One exception to the above rule is the COLROW subroutine. This routine permits the number of columns and rows on the screen to be easily changed without affecting the various other initialization parameters. The A register contains the column limit and the X register the row limit. COLROW sets these limits and recalculates the screen window.

4. **Control Z Feature:** A command is provided which permits data to be read from the screen by BASIC, Editors, the Monitor, etcetera. This feature only works if input is via the ASCII keyboard through the ASK Keyboard service. The function is simple: whenever a **↑Z** is encountered on input from the keyboard, the character at the current cursor position is read, the cursor is incremented to the next position, and the character which was on the screen is passed back to the calling routine. This feature makes it easy to edit lines in BASIC or any other program, by simply moving the cursor to the desired position, "reading" characters from the screen with the **↑Z**, typing in new characters wherever desired, and so forth. Try it, you'll like it!

#### **A Final Word**

This is the first release of the ASK VIDEO PLUS Software package. While every effort has been made to make it "perfect", I am sure that it contains some mistakes. The program should work without too much difficulty, but may have some bugs. If you find any serious bugs in the program or the documentation, or if you have any suggestions to improve the program or documentation, please be sure that all such input would be appreciated. Send your comments to:

### Updated Cassette Information

Since the publication of the VIDEO PLUS Manual, we have decided to change the material on the cassette tape slightly, making it more useful to the typical user. The new cassette tape is organized as follows:

1. The first program is still the Memory Plus Test and has ID 10.
2. The second program is still the Video Plus Subroutines assembled for 2000.
3. The third program has been totally changed. It is now the Video Plus Subroutines assembled at 0C00. This is intended for use with the AIM 65 or SYM 1 each of which have the capability of adding memory "on-board" up to 0FFF. This version of the Subroutines resides from 0C00 to about 0FA0. The program listings are equivalent to those provided in this manual, with the obvious exception of the address changes. Location 0C00 = 2000, 0C01 = 2001, .... The Example Program has been modified to work with the AIM 65. It is:

0F8B	20 22 0C	TRYIT	JSR	INIT	INITIALIZE CRT CONTROLLER
0F8E	20 93 E9	LOOP	JSR	INALL	GET CHARACTER FROM AIM
0F91	20 B1 0C		JSR	CONTRL	SERVICE CONTROL CODES
0F94	B0 F8		BCS	LOOP	CHARACTER SERVICED
0F96	20 0A 0F		JSR	WINC	WRITE NORMAL CHARACTER
0F99	90 F3		BCC	LOOP	NOT AT END OF DISPLAY
0F9B	20 9B 0D		JSR	UPSCRL	SCROLL UP AT END OF DISPLAY
0F9E	4C 8E 0F		JMP	LOOP	AND REPEAT

4. The fourth program is still the Video Plus Subroutines assembled for 5820 to be used in the EPROM. Two notes:
  - A. The code will load starting at 2000 and ending at 23A0 so that it may be copied into EPROM using the EPROM programming facilities of MEMORY PLUS. The copy parameters are:

0000	00	Low Start
0001	20	High Start
0002	20	EPROM Low
0003	00	EPROM High
0004	A0	Low End
0005	83	High End

- B. The starting address of the Example will be at 5B9B, not 5B99 as listed in the Video Plus Manual.
5. All of the programs are recorded in standard KIM format.
