BUILD THE ALTAIR 8800 MINICOMPUTER

Practical use of the computer, including programming

BY H. EDWARD ROBERTS AND WILLIAM YATES

AST MONTH, we discussed the various subassemblies used in the basic Altair 8800 computer, went into details on how it is assembled, and listed a few applications. Here, we will describe a test program to be used in checking operation and then focus on practical uses and go through a software example to familiarize you with some operating procedures.

Test Program. The following simple program is used for initial testing of the computer's operation. It also illustrates how a program is loaded and run. The selected program will add two numbers stored at address locations 128 and 129 and store the result at address location 130. The procedure is as follows:

Set the power switch to on and momentarily toggle the RESET switch. (Note: Excluding the power switch, all bottom-row switches on the front panel are spring-loaded, momentaryaction types. The switches automatically return to their center-off positions when released from either of their operate positions. When instructed to operate any of the bottom row switches, momentarily throw it to the position indicated and release it.)

Set address switches A0 through A15 all to the 0 positions (down). Operate the EXAMINE switch, which should cause address LED's A0

through A15 to extinguish to indicate that location 0 is ready. (Some of the data LED's, D0 through D7, might be illuminated, indicating the current contents at location 0.)

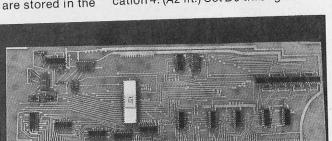

3 Next, store the load accumulator instruction at location 0 by using the binary number for 58 (00111010). Set this binary input up by using switches D0 through D7, with a 1 represented by the switch in the up position and a 0 with the switch in the down position. Hence the switch sequence for 00111010 would be: D7 down, D6 down, D5 up, D4 up, D3 up, D2 down, D1 up, D0 down. Store this number at location 0 by operating the DEPOSIT switch. The D0 through D7 LED's should now match these settings, with a lighted LED indicating a 1 and a darkened LED indicating a 0. None of the A0-A15 LED's should be on indicating location 0. The load accumulator instruction now tells the computer that the next two entries will be an address number (16 bits). Upon program execution, the data stored at that address number will be transferred to the accumulator.

Address numbers, such as address 128, are expressed in 16-bit binary format. The least-significant bits (last eight) are stored in the first memory location following the load accumulator instruction, while the most-significant bits are stored in the

second memory location. Set D0 through D7 for 10000000 (128) and operate the DEPOSIT NEXT switch. This number is now stored, in binary form, at memory location 1. (A0 LED should be lit indicating location 1.) Set D0 through D7 all to 0 and operate the DEPOSIT NEXT switch. The all-zero binary number is now stored at memory location 2 (A1 LED is lit) and the computer has been instructed to put the contents of address 128 into the accumulator.

5 To add a second number to the current number stored in the accumulator, the computer must be instructed to transfer the current number to one of the general-purpose registers. In this example, we will use register B. The instruction used is "move A to B," where A is the accumulator. The code for this instruction is 01000111, set up with switches D0 through D7. Operate the DEPOSIT NEXT switch. The instruction "move A to B" is now stored at memory location 3. (A1 and A0 lit.)

6 Now, instruct the computer to load the data from address 129 into the accumulator. This procedure is identical to that outlined in steps 3 and 4 above. Set switches D0 through D7 for 00111010 and operate the DEPOSIT NEXT switch. The load accumulator instruction is now stored at memory location 4. (A2 lit.) Set D0 through D7 for

10000001 (129) and operate the DE-POSIT NEXT switch to store this number at memory location 5. (A2, A0 lit) Then set D0 through D7 all to 0 and operate the DEPOSIT NEXT switch to store the all-zero number at memory location 6 (A2, A1 lit).

Store the add instruction at memory location 7 by setting D0 through D7 for 10000000 (128) and operating the DEPOSIT NEXT switch. When executed, this instruction adds the number in the accumulator to the number stored in register B and places the result in the accumulator (A2, A1, A0 lit).

8 To store the result at address 130, first store the instruction at memory location 8 by setting D0 through D7 for 00110010 and operating the DEPOSIT NEXT switch (A3 lit). Set D0 through D7 for 10000010 and operate the DEPOSIT NEXT switch. The least-significant eight bits of address 129 are now stored at memory location 9 (A3, A0 lit) Set D0 through D7 to 0 and operate the DEPOSIT NEXT switch. The most-significant eight bits of address 129 are now stored at memory location 10 (A3, A1 lit).

9 A program that adds the contents of address 128 to the contents of address 129 and stores the result in address 130 has now been loaded into the computer. With the use of a "jump" instruction, you can now create a program loop that will direct the computer back to memory location 0 and allow repeating this addition procedure continuously for as long as desired. Store the jump instruction at memory location 11 by setting D0 through D7 for 11000011 and operating the DEPOSIT NEXT switch (A3, A1, A0 lit). Set D0 through D7 to 0 and operate the DEPOSIT NEXT switch twice. The 16-bit address 0 is now stored at memory locations 12 and 13 (A3, A2, A0 lit).

Before we can run this program, we

have to load the two numbers we want A15 to 0 and operate the EXAMINE added into addresses 128 and 129. For example, if we wanted to add 12 to 8, the procedure would be as follows:

Set address switches A0 through A15 for 0000000010000000 (128) and operate the EXAMINE switch (A7 lit). Set D0 through D7 for binary 12 (00001100) and operate the DEPOSIT will display the sum of the two numswitch (A7 still lit). Set D0 through D7 for binary 8 (00001000) and operate the DEPOSIT NEXT switch. The binary numbers for 12 and 8 are now stored at address locations 128 and 129, respectively (A7, A0 lit).

switch (all A LED's are off). Operate the RUN switch, and the program will execute at a rate of about 30,000 times per second. Operate the STOP switch. Set the address switches to address 130 (10000010) and operate the EXAMINE switch. LED's D0 through D7 bers added, which is 20, in binary format (00010100).

Basics of Programming. If you have never done any programming, it may seem a little mysterious at first, Set address switches A0 through but the basic ideas of programming

GLOSSARY OF COMPUTER JARGON

Access time - Time interval between the instant at which information is called for storage and the instant at which delivery is complete.

Accumulator - Part of the logicalarithmetic unit of a computer used for intermediate storage, to form algebraic sums, or other intermediate operations. Address - Label, name, or number identifying a register, location, or unit

where information is stored. Assembler - Translates input symbolic codes into machine instructions. Bit — Abbreviation of binary digit; a single character in a binary number.

Buffer — Isolating circuit used to avoid reaction of a driven circuit upon its drivina circuit.

Byte — Group of binary digits usually operated upon as a unit. Usually shorter than a word.

Clock — Time-keeping device used to synchronize the computer.

Data — Basic elements of information which can be processed or produced by a computer.

Hold - Function of retaining information in one storage device after transferring it to another device, in contrast to

Instruction — Coded program step that tells the computer what to do for a single operation in a program.

Interrupt — Break in the normal flow of a system or routine such that the

flow can be resumed from that point at a later time

Jump - Depart from the normal sequence of executing instruction in a computer (synonymous with branch).

Memory - Storage. A device that holds information that can be extracted at a

Processor — Device capable of receiving data, manipulating it, supplying results usually of an internally stored pro-

Programming — Art of reducing the plan for the solution of a problem to machine-sensible instructions.

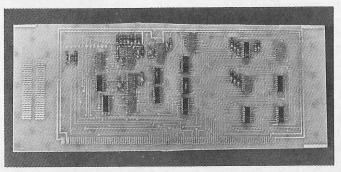

Register — Device for the temporary storage of one or more words to facilitate arithmetical, logical, or transferral operations.

Stack - Portion of a computer memory and/or registers used to temporarily hold information.

Subroutine - Set of instructions in machine code to direct the computer to carry out a well-defined mathematical or logical operation; a part of a routine.

Word - Set of characters that occupies one storage location and is treated by the computer as a unit and is transported as such. Word lengths are fixed or variable, depending on the particular computer being used.

Defining the Problem. This is by far the hardest part of the programming. Don't worry about the computer or the computer language when doing this part of the preparation. Simply decide what is required to do the job you want to accomplish.

computer and computer language have nothing to do with this step, either. It involves outlining a step-bystep procedure to achieve the desired results and getting it down on paper.

Writing the Program. Once you are familiar with programming, you will find that this step is the simplest. It is merely a matter of translating step 2 into the appropriate language.

There are many books available on programming. Some of them are quite good and are particularly useful for learning techniques such as flow programming, looping, etc. However, in essence, they can all be boiled down to the three steps above.

Software Example. To get a feel for what programming the Altair 8800 is like, let's go through a sample program, which is similar to the test program that we first went through to check out the computer operation. Assume that we want to take the data available from input channel 6 and input channel 30 and add them, placing the result in output channel 128. The machine instructions are shown in the box.

The first instruction simply stores the data from channel 6 in register A (the accumulator). The next instruction moves this data from register A to register B. This clears A for the next

are really very straightforward and input. The third instruction brings the data from input channel 30 into the A register. The fourth instruction adds the-contents of register A (data from channel 30) to register B (data from channel 6) and puts the results back into register A. The final instruction transmits the answer from A to output channel 128. Total computer time used to perform this operation with the Altair 8800 is 18 microseconds. To Establishing an Approach. The put it another way, the computer could perform 56,000 of these operations in one second.

accumulator to output 128.

The instructions could be entered into the processor in one of three ways. The first and easiest would bewith the use of an assembler. This is essentially a piece of software that converts alphanumeric symbols to machine language (binary code). For example, the assembler would convert our first instruction (IN 6) to the correct binary code. The problem with using an assembler is that you need a computer terminal for an input device and the assembler itself reguires about 6000 words of memory storage. If extensive program development is to take place, the assembler is a good tool to have.

The next easiest method of entering the instructions is with the use of

EXPANDING THE COMPUTER

In describing the assembly of the Altair 8800 Minicomputer in last month's article, it was noted that the interior of the cabinet provides plenty of room for expansion. The room can be used to add many functions to the basic computer. For example, the present memory board in the Altair 8800 can be expanded with the addition of three 256-word memories (Kit 8802-MS available from the manufacturer, MITS at \$34 per 256-word memory). Further additions require an expansion mother board having four connectors that can accommodate any four memory or input-output (I-O) cards. This expansion board (Kit 8800-EB) is available for \$44, while a 4K dynamic memory card (Kit 8840-MC) costs \$198. Various other kits-a vectored interrupt card and a real-time clock, among them-are also available.

the Very Low Cost Terminal featured in the December 1974 issue of POPULAR ELECTRONICS. With this terminal, the instructions could be entered by using the octal code. The procedure would be to write the program in assembly language and then enter the corresponding code for each instruction. This system, while not being as fast as the use of an assembler is less expensive.

The third method, using front panel entry, is of course inexpensive but time consuming.

This has been only a brief summary of the programming procedures for the computer. Complete programming information is provided with the Intel 8080 integrated circuit and with the Altair 8800 computer kit.

ABOUT THIS MONTH'S HI-FI REPORTS

The three components covered in this month's hi-fi equipment reports could easily form the heart of a very fine stereo or quadraphonic system. The general performance qualities of the Marantz 4270 receiver are more comparable to those of the better separate components than those of a receiver. Not only is it equally at home in a two-channel or four-channel system, it has built-in Dolby circuits for either FM decoding or tape recording and playback.

As for the Garrard Zero 100SB, this fine single-play record player combines the "zero tracking error" tonearm made famous by that company's Zero 100 record changer, with a new belt-driven turntable whose performance rivals more expensive units.

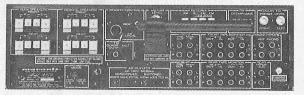

Finally, the new Ortofon VMS-20E cartridge is almost a twin of the highly regarded Ortofon M15E Super, with essentially the same performance (and sound) at a much lower price.

-Julian D. Hirsch

MARANTZ MODEL 4270 AM/FM STEREO 2-**QUADRADIAL 4 RECEIVER**

70 W/ch stereo, 25 W/ch 4-channel with built-in decoding matrix and Dolby NRS.

The Magantz Model 4270 shares many features of the other receivers

in the company's "Stereo 2-Quadradial 4" line. It's a medium power quadraphonic receiver (25 W rms/ channel) that preserves a user's ability to opt for one or more of the four-channel systems through plug-in matrix decoders and/or connection of an external CD-4 demodulator. In the stereo mode, the 4270 is transformed **FEBRUARY 1975**

into a powerful 70 W rms/channel re-

Furthermore, the 4270 features a host of refinements, such as Dolby noise-reduction circuitry for tapes and FM broadcasts; a built-in quadraphonic synthesizer for stereo software; and an optical remote control, among others.

The receiver is approximately 17% in. wide by 5% in. high by 14% in. deep (44.1x13.7x36.5 cm) and weighs 40.2 lb. (18.2 kg). Price is \$699.95. SQ and QS decoders (ranging from basic SQ to full-logic SQ and SQ/QS models) are \$49.95 to \$79.95; CD-400 adapter. \$99.95 (when purchased with receiver); remote control, \$39.95.

General Description. In addition to the conventional complement of controls and switches, the 4270 features separate tone controls-bass, midrange, and treble-for the front and rear channels. Further, complete Dolby noise-reduction facilities are available, controlled by a DOLBY switch.

When this switch is placed in one of the RECORD positions, program material is encoded or decoded for input to a tape recorder, depending on the noise-reduction capabilities of the particular tape deck. When FM DOLBY is selected, a decoder processes the FM signal for proper reception, with the added advantages of higher S/N ratio and dynamic range. Unusually complete Dolby system calibration facilities are incorporated into the receiver, including a level generator and calibrating meter that doubles as the signal-strength monitor.

Two sets of inputs and outputs for tape monitoring are included, selectable from the front panel. If only one set is used for a recorder, the other provides a convenient circuit interruption point for patching in a graphic equalizer or signal monitor.

A "flywheel" tuning control, protruding through the front panel selects the operating frequency of the tuner. Two meters, an AM/FM signal strength indicator and an FM zerocenter monitor make precise tuning adjustments possible. Three slidetype controls adjust balance between the front, rear, and front/rear channels.

Among the rear-panel inputs and outputs is an FM UADRADIAL output. This jack supplies the composite detector output for possible use with a discrete four-channel adapter, should an FCC-approved FM system be developed. Also included are screwdriver adjustments for FM Dolby level. muting, and a socket for an optional remote control unit for volume, loudness, and balance adjustments. The PREAMP OUT and AMP IN jacks, normally bridged by jumpers, provide another circuit-interruption point for signal processors, or for using the 4270 with a super-powered amp. A slide switch changes the normal 75-µs deemphasis characteristic to 25 us. for proper reception of FM Dolby broadcasts. A power mode switch selects
