communications. A synchronous orbit over the North Pole is physically impossible, so AMSAT was forced to select from compromise orbits. More than 90 per cent of the world's amateur population resides in the Northern Hemisphere, so an elliptical orbit giving maximum coverage of the Northern Hemisphere was chosen. As mentioned earlier, the apogee of the Phase III orbit will be approximately 24,000 miles over the North Pole and the perigee will be 910 miles over the South Pole. While in the Southern Hemisphere, the satellite will function much like the current OSCAR VII and D satellites.

Underscoring the international character of Project OSCAR, Phase III will be launched late in 1979 by the European Space Agency from the Guiana Space Center in French Guiana, South America. Amateurs in Japan, West Germany, Britain, and the United States are all joining in the effort to build Phase III. Currently, discussions are being held concerning the launch of a second Phase III satellite in 1980 or later aboard the Space Shuttle.

Phase III will make use of frequencies in the same general range as the mode-B and mode-J frequencies currently in use. This is in agreement with AMSAT's policy of not rendering obsolete gear currently being used for OSCAR communication.

AMSAT and the Future. If you're interested in keeping up with the latest news on the OSCAR program and helping its future development, you should consider joining AMSAT. Dues are $10 per year, which includes a subscription to the quarterly _AMSAT Newsletter_. AMSAT also engages in numerous fundraising projects to help pay the costs of the OSCAR program and will gladly supply additional information on request. The address is Box 27, Washington, DC 20044.

Be sure to report reception of any of the OSCAR's to AMSAT to get one of their QSL cards. And why stop at mere listening? A Technician class amateur license, with its leisurely five-words-per-minute code speed, allows you to work other amateurs through OSCAR. Several manufacturers are currently designing walkie-talkies to work through Phase III. Just imagine the fun of being able to hold five-hour ragchews with amateurs in Japan and Europe through a hand-held radio once Phase III is aloft! That's what the future holds when you're involved in OSCAR communications. ◇

HOW TO UPGRADE A BASIC ELF MICROCOMPUTER

TTY COMMUNICATION · TAPE CASSETTE READ/WRITE · MUSICAL PROGRAMS · FREQUENCY/TIME INTERVALS · MEMORY PRENUMBERING

BY EDWARD M. McCORMICK

IF YOU OWN a basic (256 bytes of RAM) Elf computer, for less than $5 in hardware costs you can:

- Read and write data using a conventional cassette tape machine.
- Create musical programs.
- Communicate with a TTY.
- Measure frequency/time intervals.
- Memory prenumbering.

Here's how to upgrade an Elf to accomplish the foregoing. These applications require a 2-MHz crystal, or the timing programs modified.

Cassette Storage. The "Kansas City" tape cassette standard uses 8 cycles of 2400-Hz tone for a logic "1", and 4 cycles of a 1200-Hz tone for a logic "0". Eleven bits are required for each byte. First, there is a 0 to indicate the beginning of transmission, followed by eight 1's and 0's to form the actual data byte, and finally two 1's to finish. The byte rate is about 27 per second.

The hardware required for a simple cassette interface is shown in Fig. 1. Note that a resistor network is required to reduce the Q-signal output down to the level required by the cassette recorder MIC or AUX input. The values of these resistors have to be determined by experimenting with your own recorder. (Try 47k as the value for the series resistor. You may or may not need the resistor to ground.) The transistor circuit accepts the tone data from the cassette recorder, using a 2N2222 to provide clean data for the EF2 input of the Elf.

The program shown in Table I writes the 152 bytes in locations 68 through FF

onto the tape in about six seconds. When the program runs, it first generates a 2400-Hz tone for the leader. After recording the leader for about 10 seconds, depress the IN pushbutton to initiate the data recording. At the conclusion of the data, a trailer tone should also be recorded.

Table II's program will read the bytes from the tape into locations 68 through FF. The RUN switch should be turned on only when the cassette is playing back the 2400-Hz leader. When the data is encountered, it will be displayed. The tape recorder should be stopped while on the trailer.

Depressing the IN pushbutton causes the program starting at 68 to be executed. When the RUN switch is turned off, the Elf is ready to read another program from the cassette. To re-execute the program presently residing at 68, temporarily change the byte at memory location 01 from 02 to 68.

Fig. 1. Simple interface between Elf and cassette recorder.

20-mA Interface. The circuit shown in Fig. 2 provides an interface between the Elf and a 20-mA current-loop device (such as a TTY). The signal from Q drives the current loop, while the signal from the external current-loop device drives the EF3 input of the Elf.

A program to read and write to this interface is shown in Table III. When first executed, the program from 00 through 3E causes characters read from the keyboard or tape reader to be written into successive memory locations starting at 7A. Whenever the memory is filled, or the IN pushbutton is operated, the program reverts to the section between 3F and 6F that reads from memory to the current-loop device. This program illustrates the basic input/output technique and can be adapted for specific needs.

Note that the system will read all eight bits from a byte of memory and will punch all eight bits. Similarly, all eight bits on the tape will be read to memory. However, striking a key on the TTY enters only seven information bits since it is an ASCII device. The printer will ignore the eighth (most significant bit). Thus, Elf programs must be initially entered via the switches or from a hex keypad.

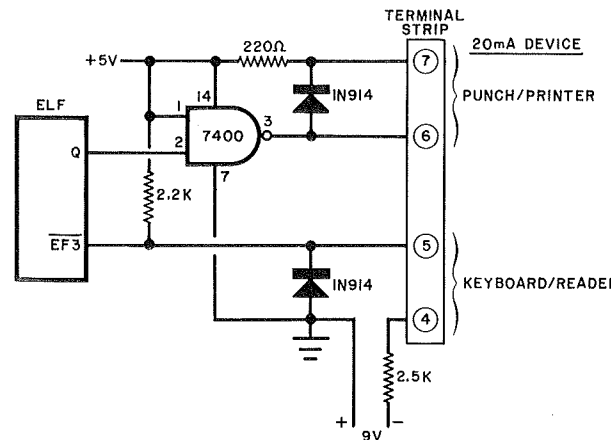

Fig. 2. Interface between Elf and a 20-mA current-loop device such as a TTY.

Memory Prenumbering. As a practical matter, it is often advantageous to "prenumber" all memory before entering data into the Elf. When the program shown in Table IV is entered and run, each memory location's contents is the address of that location. As a result, you can watch the hex display when manually entering programs to see if the next unused location is where it should be, or whether you have entered too many or too few bytes. This approach can be very useful in debugging programs.

TABLE IV. PROGRAM TO PRENUMBER MEMORY.

Loc	Instr

07	30 04

Music. It is possible to program the Elf to reproduce the notes of the musical scale by connecting a speaker system to the Q output line and using the program shown in Table V.

The music program requires two data bytes for each note played. The first byte determines the duration of the note, while the second byte determines the pitch. Table VI shows the hexadecimal values for whole-note duration and the pitch of various notes. These byte pairs must immediately follow the music program shown in Table V—that is, it must start at hex AC. To illustrate, data for the first eight bars of Neil Simon's "Feeling Groovy" is listed in Table VII.

The music tempo depends on the hex value stored in memory 77 of Table V. The larger the hex value, the slower the tempo. The usual range is from hex 10 to hex 20.

Incidentally, the music program starts at hex 68; thus it can be recorded on a cassette. However, this leaves space for only 43 notes in a basic Elf. If the program starts at 00, then 91 notes can be stored.

Frequency Counter. The input circuit used to read from a cassette (Fig. 1), can also be employed to make the Elf act as a limited range frequency counter when the program shown in Table VIII is entered and run.

When the IN pushbutton is operated, the program counts the number of cycles occuring in a one-second interval and displays the most significant byte of that count. Operating the IN pushbutton switch again displays the least significant byte to be displayed. Operating the IN switch again results in a second frequency count, etc.

The input signal should overdrive the 2N2222 to ensure clean 0's and 1's. The maximum frequency is about 5800 Hz.

TABLE IX. PROGRAM TO MEASURE TIME INTERVALS.

Loc	Instr	Remark	Loc	Instr	Remark

13	3E 12	* EF3=0	26		Storage
15	E1	Exit at end			

Interval Timer. Using a similar input technique, the program shown in Table IX allows the Elf to be used as a simple interval timer.

When the IN pushbutton is depressed, the Elf waits for the next 0-to-1 crossing, and then measures the time to the next 0-to-1 crossing. The count displayed in the hex readouts is in 16-microsecond units. Accordingly, the maximum count with this program is about one second. The program can be modified for decimal display and longer time intervals. ◇

A future issue will show other alternatives for upgrading an Elf Computer.
